Chapter 10

Default Heat Loss Coefficients

Building component heat loss coefficients are used extensively when complying with either the Component Performance or System Analysis Approach. The Prescriptive Approach only utilizes heat loss coefficients for doors, windows and skylights.

WSEC Chapter 10 lists default heat loss coefficients for hundreds of building assemblies. Heat loss coefficients are listed as default F-factors for slabs and default U-factors for most other components.

The WSEC Chapter 10 default heat loss coefficients for windows, skylights and doors should only be used when the product manufacturer or dealer cannot provide you with National Fenestration Rating Council (NFRC) tested U-factors. In most cases it will be to your advantage to contact the manufacturer to obtain NFRC tested U-factors before submitting your application for a building permit.

Component Descriptions
To assure you select the correct heat loss coefficient, it is important to read the description of the component that precedes each table. The heat loss coefficient will vary based on the construction method. Examples of construction details that will change the heat loss coefficient include framing style, siding type, slope of attic, insulation type and insulation location. The illustrations used in earlier chapters of this guide will help you visualize the written descriptions.

What to do if a building system is not listed in WSEC Chapter 10

WSEC requires that plans and specifications be submitted to the building official with all the needed supporting data. This could include detailed U-factor calculation for building systems not detailed in the Chapter 10 default heat loss coefficients. Heat loss coefficients should be calculated
using the methods detailed in the ASHRAE Handbook of Fundamentals.

Manufacturers of pre-fabricated building assemblies may have engineering staff available that will provide the required calculations.
